RADIOLOGICAL CHARACTERIZATION REPORT FOR THE 233-S PLUTONIUM CONCENTRATION FACILITY DEMOLITION PROJECT

1.0 INTRODUCTION

Information on the extent and level of radiological contamination is critical to planning for the demolition of the 233-S Plutonium Concentration Facility (233-S). Extensive radiological surveys have been performed, as well as detailed nondestructive assay measurements (NDA). However, these were deemed insufficient in two areas: 1) waste disposal planning for the purpose of minimizing transuranic waste (TRU), and 2) evaluating specific demolition methodologies and mitigation techniques to minimize the release of radiological materials during the demolition process. A sampling plan was developed (Attachment 1) to collect additional radiation dose rate measurements with the goal of correcting this deficiency. The measurements were collected using standard radiation survey instrumentation specially modified and calibrated to provide results specifically meaningful to the 233-S Demolition Project. Dose rate to activity conversion factors were determined using MicroShieldTM¹, a computerized radiation shielding program.

This report provides a detailed description of the technical basis of the modifications to the radiation survey instrumentation, its use, and limitations, and data reduction techniques (Section 2.0). In Section 3.0, the results are presented with respect to eliminating the deficiencies identified above. Estimates of the total TRU waste present in 233-S will be provided, in addition to the mass of TRU radionuclides on facility surfaces. Conclusions are presented in Section 4.0.

2.0 Materials and Methods

Radiation dose rate measurements were collected using standard radiation survey instrumentation. Sample locations on facility surfaces specified in the sampling plan (Attachment 1) were identified on maps for use in recording data in the field. Surfaces requiring detailed survey grids were marked prior to data collection using chalk lines. Both contact and field (30 cm) measurements were collected. The distance was carefully determined prior to recording the measurement to ensure repeatability.

2.1 Survey Instrument Details

Three instrument types were modified for ²⁴¹AM dose rate measurements at 233-S. These were a Ludlum 44-2 1"X1" NaI detector with an Eberline E-600 meter, a Ludlum Model 19 microrem meter (also a 1"X1" NaI detector internal to a meter), and a Bicron microrem meter (tissue equivalent dose rate meter).

¹ Microshield is a trademark of Grove Engineering (A Framatome ANP Company), Olney, Maryland

The calibration/instrument services group at PNNL performed the modifications and calibrations. The detector of each instrument was shielded with 1/16" (1.59 mm) of lead on all sides except the "front" of the detector. The tenth-value layer for 70 keV potential x-ray beams is 0.52mm of lead. The 70 keV potential was selected from the published tables instead of 50 keV since the table used some attenuating layer to harden the beam and 70 keV potential will give x-rays ranging from 70 keV down. Since gamma and x-rays will behave identically and 70 keV potential will create x-rays up to 70 keV, this value should be conservative but close to the actual tenth-value layer thickness for the gamma emissions from ^{241}Am . This would reduce the response of the detectors by a factor of 1000 from all directions but the unshielded end making them quite directional. Testing at PNNL showed this to be the case; a ~200 μrem field measured from the responsive end was too low to measure from all other directions with the shielded detector.

The instruments were calibrated using a NIST traceable ^{241}Am well source at PNNL at all scales. All instruments were adjusted so that the reading on the instrument matched the calculated dose, no correction factors were necessary. Wide beam geometry was used, and no unfavorable geometry (point, narrow beam) corrections were developed. PNNL agreed that 30 cm distance from an area source should match this calibration well.

2.2 Data Reduction Methods

Dose rate data was collected at the sampling locations identified in Attachment 1 and using the instrumentation described in Section 2.1, above. Conversion factors are necessary to relate the measured dose rate information activity present. Since the measured dose rate results primarily from photons emitted by ^{241}Am the conversion factors must also relate the measured dose rate the total activity of TRU radionuclides. The conversion factors are based on the shielding model results, physical and radiological properties of the radionuclides present, as well as the isotopic activity and weight distributions for contamination found in 233-S. A detailed description of the conversion derivation is provided in Attachment 2. The factors are summarized in Table 2-1.

Table 2-1 Conversion Factors for Dose Rate Data Reduction

C. F.	Purpose	Factor	Units
C_{241}	Relates ^{241}Am dose rate to activity	2.37e+05	$\frac{d/m}{100\text{cm}^2} (^{241}\text{Am})$ $\mu\text{rem}/\text{h}$
f_{TRU}	Relates ^{241}Am activity to total TRU	2.39	$\frac{d/m(TRU)}{d/m(^{241}\text{Am})}$
SpA_{TRU}	Relates TRU activity to TRU mass	0.126	$\frac{\text{Ci}(TRU)}{g(TRU)}$

Each sample location is comprised of 2421 cm² of surface area. This area is defined by the distance from the surface to be measured and the solid angle formed around the detector axis by the lead collimator. The total TRU activity is calculated from the dose rate determined at 30 cm from that location using the values in Table 2-1:

$$A_{TRU} = \frac{DR(\frac{\mu\text{rem}}{\text{h}}) \times CF_{241} \times f_{TRU} \times 24.21}{2.22e+03 \frac{d/m}{nCi}} = nCi(TRU)$$

Where: 24.21 = conversion from activity per 100 cm² to total in sample region

The total mass, W_{TRU} , of TRU in the sample region is calculated:

$$W_{TRU} = A_{TRU} (nCi) \times 10^{-9} \frac{Ci}{nCi} \times SpA_{TRU} = g(TRU)$$

3.0 CHARACTERIZATION RESULTS

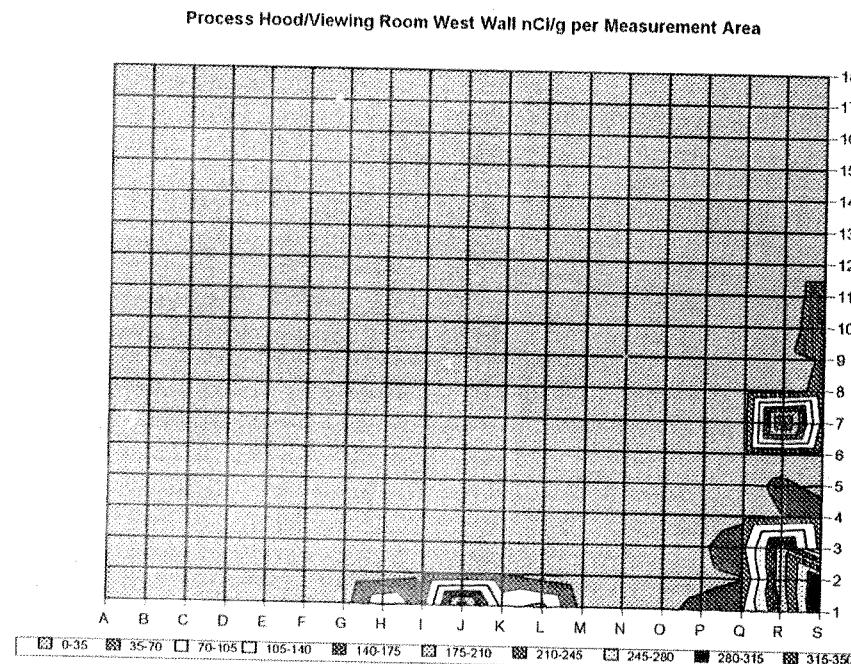

This section presents the characterization results with regard to estimates for the activity and mass TRU radionuclides. This information will be presented within the context of estimating the volume of TRU waste generated during the demolition of 233-S and quantifying the source term for use in calculating on-site and off-site impacts from potential releases.

3.1 TRU Waste Estimates

TRU waste estimations were determined by taking the total nCi of calculated activity and dividing by the mass for a particular shot area.

The limit for the ERDF (Environmental Restoration Disposal Facility) is ~92.5 nCi/g. To provide a degree of conservatism to the analysis, a value of 70 nCi/g was used to help define the TRU segments. This method identified 3 primary TRU segments on the West Wall of the Process Hood, represented by the areas >70 nCi/g (Figure 3-1).

Figure 3-1

There were also three areas on the North Wall of the Process Hood that contained >70 nCi/g of material. Two of those areas were very small (see coordinates A7 and A10 on Figure 3-2), with activities between 70 and 105 nCi/g and when packaged for disposal will be well below 70 nCi/g.

The Second floor of the stairwell on the east wall contains an isolated spot at 315-350 nCi/g (Figure 3-3). This area is well below 70 nCi/g as a segment packaged for disposal. All other areas of the building analyzed contained no measurements that were significantly above background, and do not contain TRU waste.

Figure 3-2

Process Hood/Viewing Room North Wall nCi/g in Measurement Area

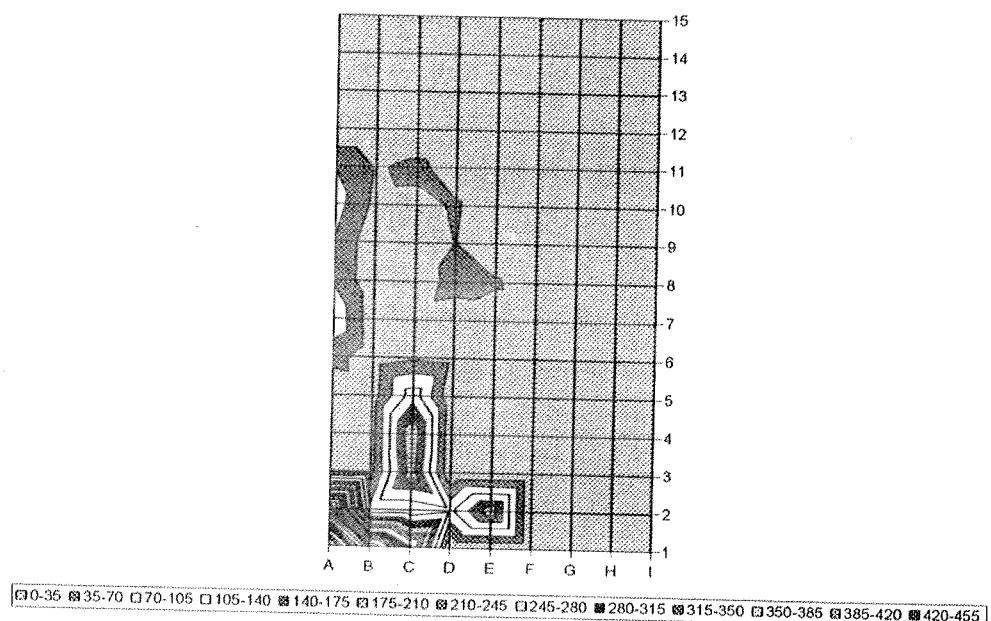

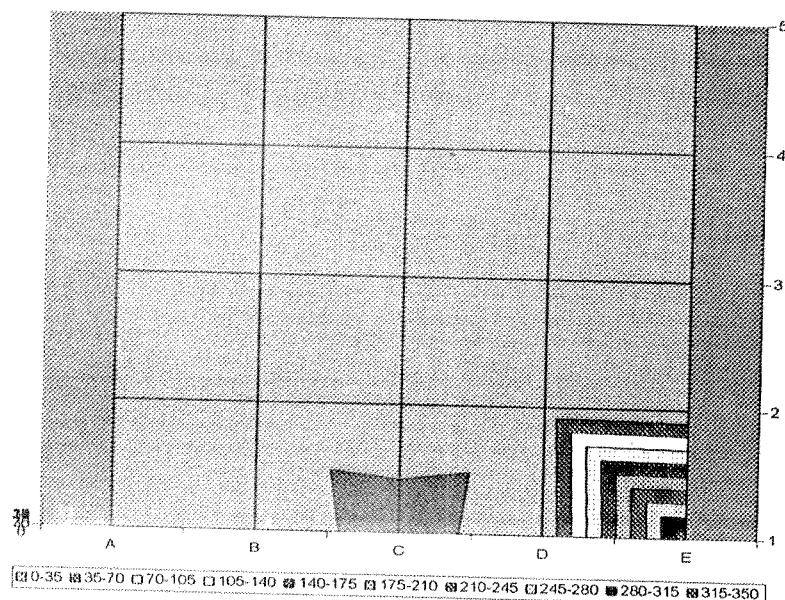

Figure 3-3

Stairwell 2nd Level Walls nCi/g Measurement Area

3.2 Release Source Term Estimates

The total TRU mass reported for each surface (wall or ceiling) was determined using a stepwise process.

1. The total surface area was divided by the total number of measurements collected on that surface to provide the area related to each measurement.
2. The determined for the measurement area of 2421 cm^2 is applied the larger area determined in Step 1, above.
3. The results from Step 2 are summed for each surface to provide the total activity or mass for that surface.
4. Process Hood areas where measurements were collected utilizing the 0.5 meter x 0.5 meter grid were treated as unique from other areas on the same surface.

The method can be described mathematically as follows:

$$W_s = \sum \left(\frac{A_s}{N} \times \frac{W_i}{2421 \text{ cm}^2} \right)$$

Where:
 W_s = Total TRU mass on Surface, S
 N = Number of measurements collected on Surface, S
 A_s = Area of Surface S, cm^2
 W_i = TRU mass determined from measurement, i

The TRU mass determined from each measurement W_i is provided in Attachment 3. The total TRU mass for each area of the 233-S Facility are presented in Table 3-1.

Table 3-1 TRU Mass Estimates for 233-S Locations

Location	TRU (grams)
Can Storage Room	0.061
SWP/Equipment Room	0.054
Pipe Gallery	0.141
PR Can Storage	0.039
PR Can Loadout	0.081
Stairwell - 1 st Floor Wall	0.024
Stairwell - 2 nd Floor Wall	0.055
Stairwell - 3 rd Floor Wall	0.026
Stairwell - 4 th Floor Wall	0.018

Process Hood - West Wall	5.682
Process Hood - North Wall	6.175
Process Hood - South Wall	0.038
Process Hood - East Wall	0.828
Process Hood - Ceiling	0.037
Total	13.39

4.0 CONCLUSIONS

This report describes the characterization method and results for the 233-S Plutonium Concentration Facility. The purpose of the characterization was to determine the total activity or mass of radionuclides on the walls of the facility prior to demolition. Remediation of radioactivity present on the facility floor is not included in the present demolition project.

The method relies on the detection of photons emitted by ^{241}Am present on the contaminated surfaces. In this respect it is similar to the NDA methodology used previously to provide estimates of radionuclide activity or mass present in the facility (Clinton, 2003). However, the total mass of alpha-emitting radionuclides estimated by this method is 13.39 grams, compared to the previous estimate of 46.2 grams. This difference is believed to primarily result for the following reasons:

1. A layer of concrete was added to the floor of the Process Hood after the previous study was conducted reducing the contribution from contamination on the floor to measurement of the wall activity.
2. The photon detector was modified to make its response highly directional. This modification allowed the more accurate determination of activity on a given surface by reducing interference from activity adjacent surfaces.

3. A method was developed for more accurately determining subtracting the contribution from background radiation levels.
4. Excess radioactive materials (waste, equipment, etc) were removed prior to collecting the current measurements.

233-S PLUTONIUM CONCENTRATION FACILITY
DEMOLITION PROJECT - RADIOLOGICAL SURVEY PLAN

1.0 INTRODUCTION

The planning effort for the 233-S Plutonium Concentration Facility (233-S) requires additional information with regard to the extent and level of radiological contamination. Extensive radiological surveys have been performed, as well as detailed nondestructive assay measurements (NDA). However, these are insufficient in two areas: 1) waste disposal planning for the purpose of minimizing transuranic waste (TRU), and 2) evaluating specific demolition methodologies and mitigation techniques to minimize the release of radiological materials during the demolition process.

Radiological surveys were performed for the purpose of radiological safety. For this reason, a large number of the data are reported as being less than a certain exposure level of interest, i.e. 5 milliroentgens per hour (mR/h). Use of these data would result in a large overestimation of the level of contamination for the areas where the measurements were collected. The quantity of TRU waste would be overestimated by a factor of at least 10. Planning for demolition will be more restrictive than actually necessary leading to an increase in project cost and schedule.

Similarly, the NDA data provides an upper bound to the mass of radionuclides actually thought to exist in 233-S. This conservatism resulted in assumptions required by uncertainties related to measurement conditions, as well as measurement interference from radioactive materials other than those of interest. Use of this data alone for waste disposal or demolition decisions will also lead to increased project costs and schedule.

Neither data set provides sufficient information to determine the areal extent of several hot spots within 233-S. This determination is necessary to minimize the amount of waste designated TRU.

This plan will describe the sampling methods and locations required to collect radiological survey data sufficient to achieve the following goals:

1. Characterize areas with "less than" survey data with regard to waste designation, i.e. TRU or low-level waste.
2. Determine the extent of hot spots to provide a better estimate of the quantity of TRU waste.
3. Characterize all areas sufficiently to either confirm or refine the radionuclide activity estimates based on NDA measurements.

2.0 APPROACH

The radiological survey will provide radiological exposure rate data collected at the specific locations identified in Section 3.0 and using the instrumentation described below. The exposure rate at the specified sampling locations will be measured on contact with the surface and/or at a distance of 30 cm. A means of reliably determining the appropriate distance will be provided to the Radiological Control Technicians performing the measurements. Scanning measurements may be utilized as needed to locate areas of elevated activity.

2.1 Sampling Method

Exposure rates less than or equal to 50 mR/h will be measured using a Ludlum Model 19 MicroR Meter, Eberline E-600 rate meter equipped with a Ludlum Model 44-2 probe, a Bicron microrem meter, or other appropriate radiation protection instrumentation. The detectors for the Ludlum instruments consist of a 1 inch by 1-inch Sodium Iodide detector coupled to a photomultiplier tube. The Bicron meter is a plastic scintillator detector. The detectors are shielded with 1/16 inch lead sheet on all sides except the front to minimize interference from contaminants on surfaces other than the one being measured. The detectors will be calibrated to the ~60 keV gamma emitted by ^{241}Am , the primary gamma-emitting radionuclide present. The background exposure rate will be determined by placing a 1/16 inch lead shield over the unshielded face of the detector and recording the reading. The additional shield effectively eliminates all exposure due to ^{241}Am but has little effect on higher energy photons (i.e., cosmic rays, ^{137}Cs , or radon daughters). The background exposure rate will be determined for each area where measurements are taken.

Exposure rates greater than 50 mR/h will be measured using an ionization chamber. The aluminum/phenolic material of the detector chamber will provide some directional capability for the instrument. The instrument will provide a verification of previous measurements.

Measurements will require at least 2 individuals; one to verify sampling locations and record data, and one to operate the instrument and convey the readings.

2.2 Data Analysis

A conversion factor relating exposure rate to curies of ^{241}Am will be calculated using Microshield[™]², a computer based shielding code. The activities of other radioisotopes will be determined using the isotopic distribution previously reported in the 233-S Safety Basis.

² Microshield is a trademark of Grove Engineering (A Framatome ANP Company), Olney, Maryland

2.3 Preliminary Activities

Prior to implementing the sampling plan described below, packaged waste within 233-S should be removed/moved, as should any equipment, materials or other items that could impede the performance of the surveys or increase the radiation background. A layer of grout will be poured on the floor of the Viewing Room and Process Hood to reduce the radiation background. The expected grout thickness is 10 inches and 6 inches in the Viewing Room and Process Hood, respectively.

3.0 SURVEY PLAN

This section describes the locations where radiation exposure rate data will be taken, the type of measurement required, and data/information recording requirements. The measurements may be done in any order as well as concurrently and repeated as necessary.

3.1 Can Storage Room

The Can Storage Room is currently posted as a Radiological Buffer Area with no measurable radiation exposure utilizing standard radiation survey instruments. For this reason, it is believed that contamination, if any, will be evenly distributed and at low levels.

Static Surveys

Radiation exposure rate readings will be obtained at contact and 30 cm from the approximate midpoint of each wall, and the ceiling. The measurements will be recorded on a radiological survey report form (BD-6000-010).

Scan Surveys

A scan survey will be performed at contact along the joints of the wall panel. If areas of elevated contamination are discovered (as compared to the adjacent wall), static measurements will be obtained at contact and 30 cm. The approximate location and extent of the elevated activity, along with the static measurements will be recorded on a radiological survey report form (BD-6000-010).

3.2 PR Can Storage Room

The PR Can Storage Room is used as an access/egress route for the PR Can Loadout Room. The north one-half of the room is posted as a Radiological Buffer Area. The south one-half of the room contains a containment tent used which is posted as a high contamination and airborne radioactivity area. Radiological surveys indicate that contamination is evenly distributed over the PR Can Storage Room walls and ceiling.

Static Surveys

Radiation exposure rate readings will be obtained at contact and 30 cm from the approximate midpoint of each wall and the ceiling. The measurements will be recorded on a radiological survey report form (BD-6000-010).

Scan Surveys

A scan survey will be performed at contact along the joints of the wall panel. If areas of elevated contamination are discovered (as compared to the adjacent wall), static measurements will be obtained at contact and 30 cm. The approximate location and extent of the elevated activity, along with the static measurements will be recorded on a radiological survey report form (BD-6000-010).

3.3 PR Can Loadout Room

The PR Can Loadout Room is posted as a high contamination, airborne radioactivity, and radiation area. It is assumed that the contamination is primarily uniformly distributed.

Static Surveys

A measurement collection grid will be established on the room surfaces by equally dividing each surface into four equal sections. Radiation exposure rate measurements will be collected at contact and 30 cm at the node (four corners and center) of each grid. The room surfaces are described below:

1. On the section of the south wall between the east wall and the intersection of the Process Hood west wall.
2. On the section of the south wall between west wall and the intersection of the Process Hood west wall.
3. On the entire west wall
4. On the entire north wall
5. On the entire ceiling

The measurements will be recorded on a radiological survey report form (BD-6000-010).

Scan Surveys

No scan surveys are required for the PR Can Loadout Room.

3.4 SWP Change Room and Equipment Room

The SWP Change Room and Mechanical Room are posted as a Radioactive Material Area. Radiological survey data indicates that the contamination is uniformly distributed.

Static Surveys

Radiation exposure rate measurements will be collected at contact and at 30 cm. in the following locations:

1. The east wall of the SWP Change Room, midway between north wall and the entrance to the PR Can Loadout Room.
2. The west Wall of the SWP Change Room, midway between the north entrance and the south wall.
3. The midpoint of the east wall of the Equipment Room.
4. The midpoint of the west wall of the Equipment Room.
5. The midpoint of the SWP Change Room Ceiling
6. The midpoint of the Equipment Room Ceiling.

The measurements will be recorded on a radiological survey report form (BD-6000-010).

Scan Surveys

No scan surveys are required for the SWP Change Room and Equipment Room.

3.5 Pipe Gallery

The Pipe Gallery is a High Contamination and Airborne Radioactivity Area. There are two known areas of elevated contamination, a hot spot, and the area around a junction box on the east wall. The remainder of the contamination is assumed to be primarily uniformly distributed.

Static Surveys

A measurement collection grid will be established on the room surfaces by equally dividing each surface into four equal sections. Radiation exposure rate measurements will be collected at contact and 30 cm at the node (four corners and center) of each grid. The room surfaces to be surveyed are the west, south, and east walls and the ceiling.

The measurements will be recorded on a radiological survey report form (BD-6000-010).

Scan Surveys

A scan survey will be performed at hot spot and junction box to determine the extent of the elevate activity. Static measurements will be taken at contact and 30 cm from the center of each area. The approximate location and extent of the elevated activity, along with the static measurements will be recorded on a radiological survey report form (BD-6000-010).

3.6 Process Hood/Viewing Room

The Process Hood/Viewing Room areas are the most highly contaminated of the entire 233-S Facility. The bulk of the contamination is thought to exist in areas of the north and west walls on the first and second levels. Contamination on the walls outside of these areas is much lower activity and is assumed to be evenly distributed. The main sampling goal in these areas is to better define the extent of the contamination for waste designation purposes. Sampling grids will be established over the Process Hood/Viewing Room surfaces as described below:

1. A 0.5 meter x 0.5 meter sampling grid will be established on the first two levels of the north wall and west walls.
2. The area comprised of the third and fourth levels of the north and west walls will be equally divided into four surfaces.
3. A 0.5 meter x 0.5 meter sampling grid will be established on the lower north quadrant of the third level of the west wall.
4. A 0.5 meter x 0.5 meter sampling grid will be established on the first level of the south wall.
5. The area comprised of the second, third, and fourth levels of the south wall will be equally divided into four surfaces.
6. The entire east wall will be equally divided into four surfaces.
7. The ceiling will be divided into four surfaces.

Static Surveys

1. Radiation exposure measurements will be collected at contact and at 0 cm over each node of the sampling grids described above. For the areas equally divided into four surfaces, the nodes are located at each corner of the grid plus the center. The measurements will be recorded on a radiological survey report form (BD-6000-010).

Scan Surveys

Scan surveys will be performed along the vertical steel I-beams attached to the north and south walls of the process hood. The survey will focus on detecting contamination that may be trapped between the I-beam and wall. The approximate location and extent of the elevated activity, along with the static measurements will be recorded on a radiological survey report form (BD-6000-010).

3.7 Stairwell

The Stairwell is a metal structure on the east side of 233-S containing stairs leading to the four levels of the facility. There is a metal landing at each level. The Stairwell is posted as a high contamination and airborne radioactivity area.

Sampling grids will be established on the north, east, south, and west walls of the Stairwell at each level (i.e., levels 1-4) by equally dividing each surface into four surfaces.

Static Surveys

Radiation exposure measurements will be collected at contact and 30 cm at the following locations:

1. At each node (each corner and the center) of the sampling grids.
2. At the middle of the metal landing on each floor.
3. At the midpoint of the Stairwell ceiling

The measurements will be recorded on a radiological survey report form (BD-6000-010).

Scan Surveys

Scan surveys will be performed along the C-channel attaching each landing to the walls at each level. The approximate location and extent of the elevated activity, along with the static measurements will be recorded on a radiological survey report form (BD-6000-010).

ATTACHMENT 2
DERIVATION OF DOSE TO ACTIVITY CONVERSION FACTORS
FOR USE IN 233-S CHARACTERIZATION.

1.0 Introduction

As described in Section 2.0 of the main body of this report, the approach to characterization of the 233-S Plutonium Concentration Facility relies on measuring the dose rate resulting from ^{241}Am present in contamination on the facility surfaces. To relate the measured information to total TRU activity, it is necessary to derive conversion factors. The converted data can then be used to make decisions regarding radioactive waste designation or the use of specific demolition methodologies. This attachment presents the basis for deriving the conversion factors.

2.0 Conversion Factor Derivation

The conversion factors derived in this attachment are based on the following information:

1. The calculated dose rate from an assumed (i.e., 1 curie) ^{241}Am evenly distributed over the area seen by the detector described in Section 2.1.
2. The known radiological and physical properties of the radionuclides believed to be present in the contamination on 233-S surfaces. The radionuclides present have been previously determined using laboratory analysis.
3. The activity and mass isotopic distribution of the radionuclides present as determined by laboratory analysis. The isotopic distributions are presented in Table 1, below.

2.1 Dose Rate to ^{241}Am Activity Determination

The dose rate at 30 cm. from 1 curie (Ci) of evenly ^{241}Am activity was calculated to be $3.867e+05$ microrem per hour ($\mu\text{rem h}^{-1}$). This value was determined using MicroShieldTM³ 5.03, a computerized shielding code. The source was modeled as a disk with an area of 2421 cm^2 . The activity concentration in the area of interest is:

$$C_a = \frac{1\text{Ci} \times 2.22e+12 \frac{\text{d}/\text{m}}{\text{Ci}}}{2421\text{cm}^2} \times 100 = 9.17e+10 \frac{\text{d}/\text{m}}{100\text{cm}^2}$$

So, the factor, CF_{241} , to convert dose rate to ^{241}Am activity is:

³ Microshield is a trademark of Grove Engineering (A Framatome ANP Company), Olney, Maryland

$$CF_{241} = \frac{9.17e+10 \frac{d/m}{100cm^2}}{3.867e+05 \frac{\mu rem}{\mu rem/h}} = 2.37e+05 \frac{d/m}{\mu rem/h}$$

2.2 Total Transuranic (TRU) Activity from the ^{241}Am Dose Rate

The isotopic activity distribution for the TRU radionuclides present in 233-S contamination is known and reported in the [Sampling and Analysis Plan]. The activity fraction, f_i , is the fractional activity of each radionuclide relative to the total activity present, such that:

$$f_i = \frac{A_i}{A_T}$$

Where: A_i = Activity of TRU isotope, i
 A_T = Total activity

The activity of ^{241}Am is determined from the measured dose rate and the method described in Section 2.1 above. Dividing each of the activity fraction values by that of ^{241}Am provides a new fraction, f_j , that relates the activity of each TRU radionuclide to ^{241}Am . The factor, f_j , is dimensionless.

$$f_j = \frac{f_i}{f_{am}} = \frac{A_i/A_T}{A_{am}/A_T} = \frac{A_i}{A_{am}}$$

Where: A_{am} = ^{241}Am activity

The fraction of the total TRU activity relative to that of ^{241}Am can be calculated by summing each of the values of f_j .

$$f_{TRU} = \sum f_j = \sum \frac{A_i}{A_{am}} = \frac{\sum A_i}{A_{am}} = \frac{A_{TRU}}{A_{am}}$$

Where: A_{TRU} = Total TRU activity
 F_{TRU} = Fraction of TRU activity relative to ^{241}Am

The values of f_i , f_j , and f_{TRU} are shown in Table A1-1.

Table A1-1. Activity Fractions of TRU Radionuclides

Radionuclide	f_i	f_j
^{238}Pu	0.077	0.293
^{239}Pu	0.190	0.722
^{240}Pu	0.099	0.376
^{242}Pu	0.0001	3.80e-04
^{241}Am	0.263	1.0
^{237}Np	5e-07	1.90e-06
	$f_{\text{TRU}} =$	2.39

Since f_{TRU} relates the total TRU activity to that of ^{241}Am , multiplying by the dose to curie conversion factor for ^{241}Am determined above will provide a conversion factor relating measured dose to total TRU activity.

$$CF_{\text{TRU}} = CF_{^{241}\text{Am}} \times f_{\text{TRU}}$$

$$CF_{\text{TRU}} = 2.39 \times 2.37e+05 \frac{d/\text{m}^2}{\mu\text{rem}/\text{h}} (^{241}\text{Am}) =$$

$$CF_{\text{TRU}} = 5.66e+05 \frac{d/\text{m}^2}{\mu\text{rem}/\text{h}} (\text{Total TRU})$$

2.3 Total TRU Mass from the ^{241}Am Dose Rate

The mass of TRU present in the area "seen" by the microR meter can be calculated using the following stepwise process. The results are summarized in Table A1-2 at the end of this section.

1. The isotopic weight distribution as determined by sampling and analysis and reported in the 233-S Authorization Basis provides the weight fraction of each radionuclide relative to the total weight of all radionuclides:

$$f_{W_i} = \frac{w_i}{w_T}$$

where: f_{W_i} = weight fraction of each TRU isotope, i , relative to the total weight of all isotopes
 w_i = weight of isotope, i
 w_T = weight of all isotopes

Summing, the $f w_i$ values for the TRU radionuclides will provide the total mass of TRU isotopes relative to the total mass:

$$\sum f w_i = \frac{\sum w_i}{w_T} = \frac{w_{TRU}}{w_T} = 0.9926$$

2. Dividing each value of $f w_i$ by 0.9926 provides the mass fraction of each TRU isotope relative to the total TRU mass:

$$\frac{w_i}{w_T} \div 0.9926 \frac{w_{TRU}}{w_T} = \frac{w_i}{w_{TRU}}$$

3. The specific activity can be used to determine the activity for each TRU isotope relative the total mass of TRU. If w_i and w_{TRU} from above have the units of grams (g):

$$\frac{A_i}{g_{TRU}} = \frac{w_i}{w_{TRU}} \left(\frac{g_i}{g_{TRU}} \right) \times SpA_i \left(\frac{Ci_i}{g_i} \right)$$

where: A_i = Activity (Ci_i) of isotope, i .
 SpA_i = Specific Activity(Ci/g) of isotope, i .

Summing the values determined above for each isotope results in an overall specific activity value relating total TRU activity to the mass of TRU. If the TRU activity is in the units, curies:

$$\sum \frac{A_i}{g_{TRU}} = \frac{A_{TRU}}{g_{TRU}} = 0.126 \frac{Ci_{TRU}}{g_{TRU}}$$

4. Using the overall specific activity calculated in Step 3, the dose rate to total TRU activity conversion factor can be transformed into a factor that will relate dose rate to TRU mass, CF_{mass} :

$$CF_{TRU} = 5.66e+03 \frac{\frac{d/m}{100\text{cm}^2}}{\frac{\mu\text{rem}}{h}} = 5.66e+03 \frac{\frac{d/m}{\mu\text{rem}\cdot\text{cm}^2}}{h}$$

$$CF_{max} = \frac{5.66e+03 \frac{d/m}{\mu\text{rem}\cdot\text{cm}^2}}{2.22e+12 \frac{d/m}{Ci}} + 0.126 \frac{Ci_{TRU}}{g_{TRU}} = 2.02e-08 \frac{g_{TRU}}{\text{cm}^2} = \\ 4.90e-05 \frac{g_{TRU}}{\text{shot}}$$

Table A1-2. Mass Fractions of TRU Radionuclides

TRU Radionuclide	fw_i (w_i/w_T)	g/g_{TRU}	SpA_i (Ci/g_i)	A_i/w_{TRU} (Ci/g_i)
^{238}Pu	0.0007	7.05e-04	17.2	.0121
^{239}Pu	.8405	8.47e-01	.0616	.0522
^{240}Pu	.1046	1.05e-01	.228	.0240
^{242}Pu	.0059	5.94e-03	3.88e-03	2.3e-05
^{241}Am	.0108	1.09e-02	3.47	.0378
^{237}Np	.0301	3.03e-02	7.02e-04	2.13e-05
	$w_{TRU}/w_T=0.9926$			$A_{TRU}/w_{TRU}=0.126$

ATTACHMENT 3

shorthand labels are used for location and portion. Survey point and portions. Survey point and readings match RSRs

Portion codes are first several characters are surface descriptor, such as eleathtell, Northwall, etc., which is followed by a point location when needed. These include uppers, mids, and lowers and combinations for more than three. Some endings require directional designators which is followed by l(eft), m(iddle), r(ight) and combinations for more than three. Some endings require directional designators
